

Situation:

F1V is building out its own React Component Library. We've just gotten started and are currently extending the Material-UI component library for our Button component. The next critical component we need to build out is a List-Card, which would accept an array of list items and a header. We like the Material-UI Card component as a base and already have the library installed in our repository, but will need to expand upon the component to add additional features.

Complete these three tasks:

1. Create a List-Card component that uses the Material-UI Card component as a base. This CardList component should accept a header prop and an items prop that renders the list items with a custom "-" before each item.
2. Include an example of the component in our main app homepage
3. Include 3 examples of the component in our Storybook style guide displaying the default component and the various props

The new component should match the specs provided by our designer, Steven. They are below:

\*\* We strongly recommend getting the component functional and examples created before getting the styling pixel perfect. Also, due to the time constraints, start with the areas of the challenge you know first then circle back to the areas you'll need to Google.

#### Bonus:

We'd also like to roll out a "Dark Theme" version of all of our components. If you finish the above, add a theme prop to the List-Card that defaults to Light Theme, but will also accept Dark Theme and render the card and contents according to the bonus specs.
